Introduction

Formation of chlorinated aromatic compounds from municipal solid waste incineration (MSWI) is known to occur on the surface of fly ash¹. Some kinds of metals act as catalysts and have an important role for the formation². To reduce the emission of chlorinated aromatic compounds from MSWI, it is necessary to find the substance inhibiting the formation or destructing them. In this research, to obtain the information more about the relation between chlorinated aromatic compounds and metals, the concentration distributions of PCBs, chlorobenzenes (CBzs) and metals by particle size of MSWI fly ash were investigated.

Materials and Methods

Fly ashes A to H were sampled from electrostatic precipitators (ESP) in eight continuous stoker type municipal solid waste incinerators. Fly ashes A, F and H were sampled from the same ESP. Each fly ash was classified into 4 fractions (over 500 μ m, 106-500 μ m, 44-106 μ m and under 44 μ m) by particle size using a sieving machine.

Before soxhlet extraction, 10 g of a fraction was treated with 200mmol-H⁺ HCl for 2 hours. Then, it was filtered under suction over a glass fiber filter and washed 3 times with distilled water. Soxhlet extraction was performed for all samples overnight (approx. 24hr) with 200 ml toluene. Extracts were cleaned up by chromatography on multi-layer silica columns and then were concentrated by a rotary evaporator and nitrogen blowing. All extracts were analyzed using HRGC/LRMS (HP6890/HP5973). A fused silica column (HP-5MS: 60m, 0.25mm i.d., 0.25 μ m film thickness) was used. D2CBzs to H6CBzs and D2CBs to O8CBs were determined. PCBs isomers were identified by the retention time and the peak pattern for congeners of a reference³. ¹³C-H6CBz and ¹³C-PCBs (#28, #52, #101, #118, #138) were used as internal standards.

Na, Mg, Al, K, Ca, Ti, Mn, Fe, Cu, Zn, Cd, Sb and Pb were measured using ICP-AES (ICPS-8000: Shimadzu) after 100mg of a fraction was digested with the mixture of 5ml of HNO₃, 2ml of HCl and 3ml of HF using a microwave oven (MDS-2000: CEM corp.). Ni, Cr, Cl, Br and S were measured using X-ray fluorescence analysis (XRF-1700: Shimadzu). Se, Hg and As were measured by instrumental neutron activation adsorption in Kyoto University research reactor. Unburned carbon content was measured by total organic carbon meter (TOC-5000: Shimadzu) after acid treatment.

Results and Discussions

The weight percents, CBzs, PCBs, Co-PCBs and unburned carbon content in each fraction of fly ash by particle size are shown in Table 1. The fraction of over 500 μ m was mainly consisted of black flakes that were generated by burning paper.

| <44 μm | 0.59 | 0.94 | 0.86 | 1.2 | 2.0 | 0.29 | 2.6 | 5.9 |
| Total | 0.94 | 1.6 | 3.6 | 3.4 | 5.8 | 1.0 | 5.4 | 2.8 |

Chlorobenzenes

Total concentration of CBzs in fly ash ranged from 130 to 960ng/g. The concentrations in both fractions of over 500 μm and under 44 μm were higher than those in other fractions except fly ash C and F. The homologue pattern of CBzs by particle size in fly ash A was shown in Fig.1. The concentrations of higher chlorinated benzenes were higher than those in other homologues. This pattern was commonly observed in all fractions and all fly ash. The amount of CBzs by particle size was calculated by multiplying the concentration of CBzs and weight of the fraction by particle size. The fraction contained the largest amount of CBzs was 44-106 μm . Although the weight of fly ash was very small and ranged from 1.1 to 12.5% in the fraction of over 500 μm , the ratio of amount in that fraction to total amount increased by 7.5 to 27.8%.

PCBs

Total concentrations of PCBs and Co-PCBs ranged from 14 to 150ng/g and 11 to 130 pg-TEQ/g, respectively. The concentrations in both fractions of over 500 μm and under 44 μm tended to be higher than those in other fractions, but the concentration pattern of PCBs by particle size was more vague than that of CBzs. The homologue pattern of PCBs by particle size in fly ash A was shown in Fig.2. The concentrations of H7CBs and O8CBs were lower than those in other homologues. Although there was no difference by the kinds of fly ash about this pattern, the change of pattern was observed by the particle size. The concentration of lower chlorinated biphenyls in the fraction of over 500 μm was higher than

Fig.1 The homologue pattern of CBzs in each fraction of fly ash

FORMATION AND SOURCES - POSTERS

that in other fractions. Therefore, the TEQ concentration of Co-PCBs was slightly different from the concentration of PCBs by particle size. The fraction contained the largest amount of PCBs was 44-106 μm . Although the ratio of amount in the fraction of over 500 μm to total amount increased in comparison to the weight percent of fly ash in that fraction, the increasing rate became small.

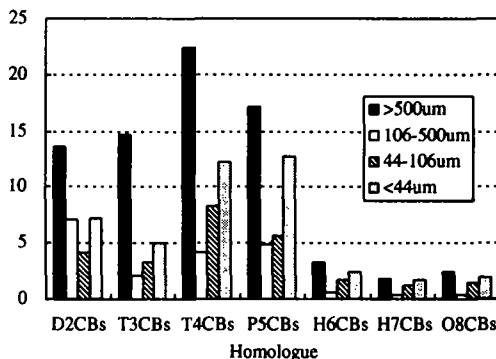

Fig.2 The homologue pattern of PCBs in each fraction of fly ash

The Relationship between CBzs, PCBs, Co-PCBs, Unburned Carbon and Elements

Correlation coefficients between CBzs, PCBs, Co-PCBs unburned carbon and elements were shown in Table 2. In all fractions mutual relationship between CBzs and Co-PCBs was sufficiently estimated. This may indicate that PCB #126, which is most toxic isomer, is formed from CBzs on the surface of fly ash. In the fraction of over 500 μm , there was no relation between chlorinated aromatics compounds and elements. In the fractions of 106-500 μm and 44-106 μm , heavy metals such as Fe, Cu, Zn, Sb and Pb had positive and close relation to CBzs or PCBs. This may be evidence that their metals promote the formation of CBzs or PCBs. On the other hand, Ti had negative relation to CBzs and PCBs so that Ti or Ti compounds was considered to act on the destruction of CBzs and PCBs or the inhibition of their formation. Before this research, unburned carbon content was estimated to have close relation to CBzs and PCBs which were incomplete combustion products, but the correlation coefficients between unburned carbon content and them was great in only a fraction of under 44 μm . In future, it is necessary to integrated further information about fly ash such as species of heavy metal or unburned carbon in order to inhibit the formation of chlorinated aromatic compounds on the surface of fly ash.
